Introduction to Computer Networks

IEEE 802.3 Ethernet

# Outline

- **Introduction**
- **Ethernet Topologies**
- **Ethernet Frame Format**
- **Ethernet MAC Protocol -- CSMA/CD**
- **802.3 Ethernet Standards**

Ethernet

- **Most successful local area networking technology of last 30 years.**

- **First widely used LAN technology**

- **kept up with speed race: 10 Mbps – 100 Gbps**

Metcalfe's Ethernet sketch

Ethernet

- **Developed in the mid-1970s by researchers at the Xerox Palo Alto Research Centers (PARC).**

- **DEC and Intel joined Xerox to define a 10-Mbps Ethernet standard in 1978.**

- **This standard formed the basis for IEEE standard 802.3**

- **More recently 802.3 has been extended to include**

  - **100-Mbps version called Fast Ethernet,**

  - **1000-Mbps version called Gigabit Ethernet,**

  - **10 Gigabit Ethernet, and also**

  - **100 Gigabit Ethernet**

Ethernet: Unreliable, Connectionless

- **Connectionless:** No handshaking between sending and receiving NICs

- **Unreliable:** receiving NIC doesn't send ACKs or NACKs to sending NIC

- Ethernet's MAC protocol: Carrier Sense Multiple Access with Collision Detection (CSMA/CD)

Outline

- **Introduction**

- **Ethernet Topologies**

- **Ethernet Frame Format**

- **Ethernet MAC Protocol -- CSMA/CD**

- **802.3 Ethernet Standards**

Bus Topology

- **Bus topology** popular through mid 90s
  - all nodes in same collision domain (can collide with each other)

同軸電纜區段（最長 500 公尺）

終端器

同軸電纜

收發器電纜（最長 50 公尺）

終端器

收發器（每區段最多接 100 個）
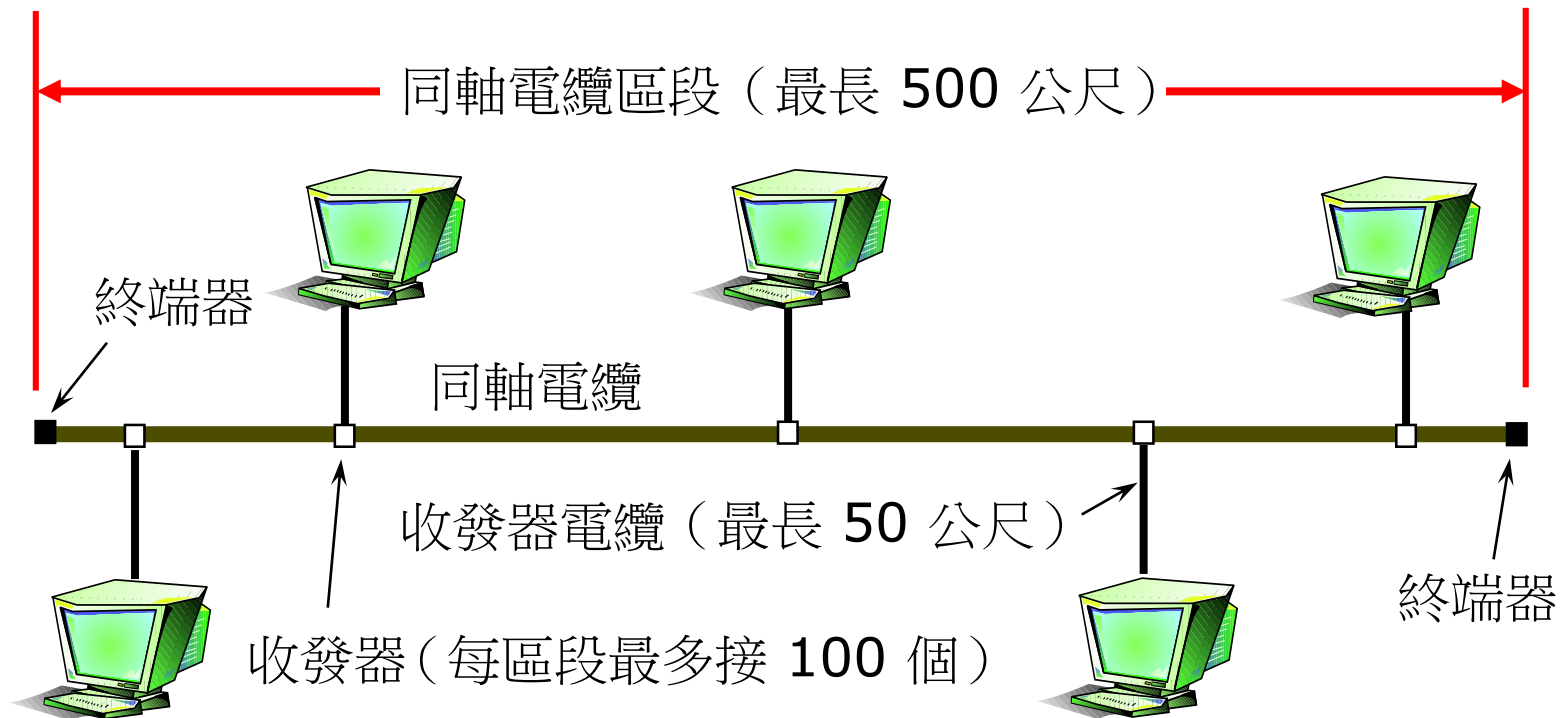

Ethernet (10Base5)

- An Ethernet segment is implemented on a coaxial cable of up to **500 m**.

- Hosts connect to an Ethernet segment by tapping into it.

- A **transceiver** (a small device directly attached to the tap) detects when the line is idle and drives signal when the host is transmitting.

- The transceiver also receives incoming signal.

- The transceiver is connected to an **Ethernet adaptor** which is plugged into the host. But now most are built in into the computers.

- The protocol is implemented on the adaptor.

Transceiver Cable

- **Each bit has a transition**
- **Allows clocks in sending and receiving nodes to synchronize to each other**

Ethernet (10Base5)

10Mbps baseband 500m

■ **Multiple Ethernet segments can be joined together by *repeaters.***

■ **A *repeater* is a device that forwards digital signals.**

■ **No more than four repeaters may be positioned between any pair of hosts.**

●   **An Ethernet has a total reach of only 2500 m.**

Ethernet (10Base2)

■ **New Technologies in Ethernet**

● **Instead of using coax cable, an Ethernet can be constructed from a thinner cable known as 10Base2 (the original was 10Base5)**

▸ **10** means the network operates at 10 Mbps

▸ **Base** means the cable is used in a baseband system

▸ **2** means that a given segment can be no longer than 200 m

Ethernet (10BaseT)

- **New Technologies in Ethernet**
  - **Another cable technology is 10BaseT**
    - **T** stands for twisted pair
    - Limited to 100 m in length
  - **With 10BaseT, the common configuration is to have several point to point segments coming out of a multiway repeater, called *Hub***

Ethernet

HUB 1

HUB 2
Ethernet Hub

Star Topology

- **Today: Star topology prevails**
  - active *switch* in center
  - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

Switch

Star topology
Ethernet-Switch

- **To speed up the transmission rate of Ethernet Hub without changing the interface cards on stations.**

- **Ether-Switch Architecture**

- **Each Ethernet port can have a transmission simultaneously.**

Outline

- **Introduction**

- **Ethernet Topologies**

- **Ethernet Frame Format**

- **Ethernet MAC Protocol -- CSMA/CD**

- **802.3 Ethernet Standards**

Ethernet Frame Format

- **Frame format**

  - Preamble (64bits): allows the receiver to synchronize with the signal (sequence of alternating 0s and 1s).

  - Source and Destination MAC Addresses (48bits each).

  - Packet type (16bits): acts as demux key to identify the higher level protocol.

  - Data (up to 1500 bytes)
    - ▸ Minimally a frame must contain at least 46 bytes of data.
    - ▸ Frame must be long enough to detect collision.

  - FCS: CRC (32bit)

7	1	6	6	2		4	bytes
Preamble	SFD	DA	SA	Type	LLC	PAD	FCS

Ethernet Frame Format

7	1	6	6	2			4	位元組
Preamble	SFD	DA	SA	TYPE	LLC	PAD	FCS	
- Preamble: (101010...1010) for Synchronization
- SFD: Start Frame Delimiter (10101011)
- DA: Destination MAC Address
- SA: Source MAC Address
- Packet type (16bits): acts as demux key to identify the higher level protocol.
- LLC-Frame: Up to 1500 bytes
- PAD: Padding when LLC-Frame < 46 bytes
- FCS: Frame Check Sequence (CRC-32)
- MAC-frame size -- from DA to FCS

- Min 64 bytes to distinguish from collision
- Max 1518 bytes to prevent dominating bandwidth

Ethernet Addresses

- **Each host on an Ethernet (in fact, every Ethernet host in the world) has a unique Ethernet Address.**

- **The address belongs to the adaptor, not the host.**
  - It is usually burnt into ROM.

- **Ethernet addresses are typically printed in a human readable format**
  - As a sequence of six numbers separated by colons.
  - Each number corresponds to 1 byte of the 6 byte address and is given by a pair of hexadecimal digits, one for each of the 4-bit nibbles in the byte
  - Leading 0s are dropped.
  - For example, 8:0:2b:e4:b1:2 is
    - 00001000 00000000 00101011 11100100 10110001 00000010

Ethernet Addresses

■ **To ensure that every adaptor gets a unique address, each manufacturer of Ethernet devices is allocated a different prefix that must be prepended to the address on every adaptor they build**

▸ **AMD has been assigned the 24bit prefix 8:0:20**
Ethernet Addresses

- **Each frame transmitted on an Ethernet is received by every adaptor connected to that Ethernet.**

- **Each adaptor recognizes those frames addressed to its address and passes only those frames on to the host.**

- **In addition to *unicast address*, an Ethernet address consisting of all 1s is treated as a *broadcast address*.**

  - All adaptors pass frames addressed to the *broadcast* address up to the host.

- **Similarly, an address that has the first bit set to 1 but is not the *broadcast* address is called a *multicast address*.**

  - A given host can program its adaptor to accept some set of *multicast* addresses.

Ethernet Addresses

- **To summarize, an Ethernet adaptor receives all frames and accepts**

  - **Frames addressed to its own address**

  - **Frames addressed to the broadcast address**

  - **Frames addressed to a multicast address if it has been instructed**

Outline

- **Introduction**
- **Ethernet Topologies**
- **Ethernet Frame Format**
- **Ethernet MAC Protocol -- CSMA/CD**
- **802.3 Ethernet Standards**

Ethernet MAC protocol

■ **Any signal placed on the Ethernet by a host is broadcast over the entire network**

- **Signal is propagated in both directions.**

- **Repeaters forward the signal on all outgoing segments.**

- **Terminators attached to the end of each segment absorb the signal.**

CSMA (Carrier Sense Multiple Access)

CSMA: listen before transmit:

If channel sensed idle: transmit entire frame

■ If channel sensed busy, defer transmission

CSMA collisions

collisions can still occur:
propagation delay means two nodes may not hear each other's transmission

collision:
entire packet transmission time wasted
CSMA/CD (Collision Detection)

CSMA/CD: carrier sensing, deferral as in CSMA

- collisions *detected* within short time

- colliding transmissions aborted, reducing channel wastage

■ Collision detection:

- Measure signal strengths, compare transmitted, received signals

CSMA/CD collision detection
CSMA/CD

- **Carrier Sense Multiple Access with Collision Detection (CSMA/CD).**

  - **A set of nodes send and receive frames over a shared link.**

  - **Carrier sense means that all nodes can distinguish between an idle and a busy link.**

  - **Collision detection means that a node listens as it transmits and can therefore detect when a frame it is transmitting has collided with a frame transmitted by another node.**

CSMA/CD

- When the adaptor has a frame to send and the **line is idle**, it transmits the frame immediately.

- When the adaptor has a frame to send and the **line is busy**, it waits for the line to go idle and then transmits immediately.

- The Ethernet is said to be **1-persistent protocol** because an adaptor with a frame to send transmits with **probability 1** whenever a busy line goes idle.

CSMA/CD

■ **Since there is no centralized control it is possible for two (or more) adaptors to begin transmitting at the same time,**

- ● **Either because both found the line to be idle,**

- ● **Or, both had been waiting for a busy line to become idle.**

■ **When this happens, the two (or more) frames are said to be *collide* on the network.**

CSMA/CD

- **Since Ethernet supports collision detection, each sender is able to determine that a collision is in progress.**

- **At the moment an adaptor detects that its frame is colliding with another, it first makes sure to transmit a 32-bit jamming sequence and then stops transmission.**

  - **Thus, a transmitter will minimally send 96 bits in the case of collision**

    ‣ **64-bit preamble + 32-bit jamming sequence**

CSMA/CD

- **One way that an adaptor will send only** **96 bits** **(called a** *runt frame***) is if the two hosts are** **close to each other**.

- **In case the two hosts are farther apart, they would have had to transmit longer, and thus send more bits, before detecting the collision.**

Collision Window

■ **The worst case scenario happens when the two hosts are at opposite ends of the Ethernet.**

■ **To know for sure that the frame its just sent did not collide with another frame, the transmitter may need to send as many as 512 bits.**

 ● Every Ethernet frame must be at least 512 bits (64 bytes) long.

   ‣ 14 bytes of header + 46 bytes of data + 4 bytes of CRC

7	1	6	6	2		4	bytes
Preamble	SFD	DA	SA	Type	LLC	PAD	FCS
Collision Window

- **Why 512 bits (64 bytes) ?**
  - **Why is its length limited to 2500 m?**
- **Collision Window = round-trip delay (2a)**

- **The farther apart two nodes are, the longer it takes for a frame sent by one to reach the other, and the network is vulnerable to collision during this time**

Collision Detection Window for CSMA/CD (=2a)

Propagation delay = a

t

A 開始傳送

A   B

$t+a-\varepsilon$

B 開始傳送

A   B

衝撞

$t+a$

B 偵測出衝撞

A   B

$t+2a-\varepsilon$

A 偵測出衝撞

A   B
Collision Window

- **A begins transmitting a frame at time t**
- **a denotes the one link latency**
- **The first bit of A's frame arrives at B at time $t + a$**
- **Suppose an instant before host A's frame arrives, host B begins to transmit its own frame**
- **B's frame will immediately collide with A's frame and this collision will be detected by host B**
- **Host B will send the 32-bit jamming sequence**
- **Host A will not know that the collision occurred until B's frame reaches it, which will happen at $t + 2a$**
- **Host A must continue to transmit until this time in order to detect the collision**
  - Host **A must transmit for $2a$** to be sure that it detects all possible collisions

Collision Window

- **Consider that a maximally configured Ethernet is 2500 m long, and there may be up to four repeaters between any two hosts, the round trip delay has been determined to be 51.2 μs**

  - **Which on 10 Mbps Ethernet corresponds to 512 bits**

  - **10 Mbps x 51.2 μs = 512 bits**

- **The other way to look at this situation,**

  - **We need to limit the Ethernet's maximum latency to a fairly small value (51.2 μs) for the access algorithm to work**

    - Hence the maximum length for the Ethernet is on the order of 2500 m.

Exponential Backoff Algorithm

- Once an adaptor has detected a collision, and stopped its transmission, it **waits a certain amount of time and tries again**.

- Each time the adaptor tries to transmit but fails, it **doubles the amount of time it waits** before trying again.

- This strategy of doubling the delay interval between each retransmission attempt is known as *Exponential Backoff*.

Exponential Backoff Algorithm

■ **The adaptor first delays either 0 or 51.2 μs, selected at random.**

■ **If this effort fails, it then waits 0, 51.2, 102.4, 153.6 μs (selected randomly) before trying again;**

   ● **This is *k* * 51.2 for *k* = 0, 1, 2, 3**

■ **After the third collision, it waits *k* * 51.2 for *k* = 0… $2^3 - 1$ (again selected at random).**

■ **In general, the algorithm randomly selects a *k* between 0 and $2^n - 1$ and waits for *k* * 51.2 μs, where *n* is the number of collisions experienced so far.**

CSMA/CD Protocol

- **Carrier Sense before transmission**

- **Carrier Sense while transmission**

- **Collision: Two or more stations transmitting simultaneously**

- **Backoff: Random delay after collision**

- **Deference: Defers transmission if channel is sensed busy**

- **Collision Window (Slot time): Round-trip propagation delay time plus some carrier sense time. In IEEE 802.3, this value is defined to be 51.2 us.**

CSMA/CD Collision Handling

■ **Collision Signal is generated by Physical layer.**

■ **Jam signal (collision enforcement): To make sure that all stations involved in the collision will detect collision. A pattern of 32 bits.**

■ **Collision backoff and retransmission method (Truncated Binary Exponential Backoff Algorithm, BEBA):**

- **n : number of collisions experienced (n <= 16)**

- **k : Min (n,10) -- Truncation**

- **r : Random delay time (unit: slot time), $0 <= r < 2^k$**
CSMA/CD Collision Handling

- **Slot time = 51.2 us.**

- **Disadvantage of BEBA:**

  - **Last-in-First-out effect**: Stations with no or few collisions will have a better chance to transmit before stations that have waited longer.

Ethernet Performance

- **Ethernets work best under lightly loaded conditions.**

- **Under heavy loads, too much of the network's capacity is wasted by collisions.**

Outline

- **Introduction**

- **Ethernet Topologies**

- **Ethernet Frame Format**

- **Ethernet MAC Protocol -- CSMA/CD**

- **802.3 Ethernet Standards**

802.3 Ethernet Standards: Link & Physical Layers

- **_Many_ different Ethernet standards**
  - **common MAC protocol (CSMA/CD) and frame format**
  - **different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1Gbps, 10Gbps, 100Gbps**
  - **different physical layer media: fiber, cable**

| application |
| transport |
| network |
| link |
| physical |

MAC protocol and frame format

100BASE-TX   100BASE-T2   100BASE-FX

100BASE-T4   100BASE-SX   100BASE-BX

copper (twister pair) physical layer   **fiber physical layer**

Summary

- **MAC Protocol -- CSMA/CD**

- **Connection less, unreliable transmission**

- **Topology from Bus to Star (switches)**

- **Half-duplex transmission in Bus topology**
  - **Work best under lightly loaded conditions**
  - **Too much collision under heavy load**

- **Full-duplex transmission in Switch topology (point-to-point)**
  - **No more collisions !!**
  - **Excellent performance (wired speed)**
